Conclusion: Contrary to prevailing expectations and our study hypothesis, we found that thiamine supplementation in hospitalized patients with encephalopathy did not improve LOS. Our results are consistent with the lack of beneficial effects of supplemental thiamine in other disease conditions such as sepsis (VITAMINS study) and congestive heart failure. We do not recommend routine thiamine supplementation in hospitalized patients.

Type: Case Report

Introduction: There are few cases of non-diverticulitis episodes of colonic perforation following kidney transplantation throughout literature. In the systematic literature review by de’Angelis et al, emergency abdominal surgery following solid organ transplantation for non-diverticulitis causes gastrointestinal perforation accounts of 9.2% of cases, and about 58% of those perforations occurred in the colon. The aim of this case series is to review the events surrounding our two cases of colonic perforation following renal transplantation in hopes to gain understanding of this rare occurrence. Consent was obtained from the patients.

Case: Since 2011, there have been two events of transverse colonic perforation in the acute post-operative period following renal transplantation occurring at this institution. Large volume intraperitoneal air observed on plain film upon work up gastrointestinal symptoms prompted urgent surgical intervention in both cases. Both patients underwent urgent exploratory laparotomy and Hartmann procedure with resection of perforated transverse colon and proximal ostomy. The first patient underwent colostomy takedown and primary colonic re-anastomosis about one year after his kidney transplant. The second patient is currently scheduled for future colostomy reversal.

Conclusion: Various theories of non-diverticular causes of colonic perforations are described in literature including cytomegalovirus enterocolitis, uremic enterocolitis, fecal impaction, and corticosteroid administration among others. Despite the lack of clear cause of perforation, it is imperative to have a high index of suspicion for these immunocompromised patients for prompt surgical treatment.

Type: Original Research

Background: Adequate control of bleeding during spine surgery is paramount to the success and efficiency of the operation. Tranexamic acid (TXA) is a systemic antifibrinolytic that is beneficial in reducing blood loss during various orthopaedic procedures. TXA’s role in posterior cervical spinal surgery, however, remains poorly described. Therefore we sought to evaluate whether prophylactic TXA administration prior to posterior cervical fusion reduces perioperative blood loss and mean operative time.

Methods: Patients undergoing three to six-level posterior cervical fusions were retrospectively enrolled into two groups. In the study group, 21 patients received TXA prior to surgery, and in the control group, 21 patients did not. Patient’s younger than 19 years old, and those undergoing surgery for infection or tumors were excluded. Intraoperative blood loss, operative time, and postoperative drain output were measured in addition to demographic data.

Results: No difference existed between groups in regards to demographics. The study group had a lower mean operative time (94 min) vs the control group (110 min), although not statistically significant (p=0.06071). Postoperative day 1 drain output was significantly lower in the study group (p<0.0239). Intraoperative blood loss, day 2, 3 and total drain output were lower in the study group but not statistically significant. There were two postoperative hematomas in the control group. No postoperative thromboembolic events occurred in either group.
