rates between the Lymph2Cx assay and the Hans and Choi algorithms were calculated.

**Results:** By the Lymph2Cx assay analysis, 36 cases (51%) were classified as GCB, 25 cases (36%) were classified as ABC and 9 cases (13%) were intermediate/unclassified. The Hans algorithm classified 37/70 cases (53%) as GCB and 33/70 cases (47%) as non-GBC. The Choi algorithm classified 14/36 cases (39%) as GCB and 22/36 cases (61%) as ABC. After excluding the 9 intermediate/unclassified cases by the Lymph2Cx assay, 61 cases classified by the Hans algorithm and 30 cases classified by the Choi algorithm were compared to the Lymph2Cx. Overall, 54 (89%) of cases classified by the Hans IHC algorithm and Lymph2Cx assay were concordant. 22 (77%) classified by the Choi algorithm and Lymph2Cx assay were concordant.

**Conclusion:** The Lymph2Cx assay is a useful tool to determine COO in DLBCL. ■

**Nontuberculous Mycobacterium (NTM) Infection in Aquatic Workers With Purified Protein Derivative (PPD) and Gold QuantiFERON Tests**

Lavanya Ravipati¹, Sarah A. Howard¹

**Mentor:** Sarah A. Howard

**Program:** Clarkson Family Medicine

**Type:** Case Report

**Background:** Nontuberculous mycobacteria (NTM) infections are commonly caused by Mycobacterium marinum and fortuitum with M. marinum more likely to cause skin infections. Aquatic environments are a potential source of contact with M. marinum and fortuitum. Patients with NTM infections may present with positive tuberculin purified protein derivative (PPD) and/or gold QuantiFERON tests. However, PPD cannot differentiate between NTM infection and other tuberculous infections caused by different mycobacterial strains. We present an asymptomatic patient who presented for further evaluation of an off-site positive PPD and gold QuantiFERON Test.

**Methods:** Patient informed consent was obtained for this case report.

**Results:** A 31 year-old, healthy, female marine biologist employed in an aquatic environment presented to the clinic with a positive PPD and a positive gold QuantiFERON test. Her job exposes her to sea creatures that maybe infected with Mycobacterium marinum and fortuitum. She denied any history that was suggestive of tuberculosis infection. A referral was made to specialist service for further evaluation at which time a repeat gold QuantiFERON test was performed and was noted to be positive. Following this work up, the patient, understanding her likelihood of having exposure to M. Marinum and fortuitum, preferred to follow a conservative treatment approach to monitor for any symptoms of active tuberculosis and seek follow up as needed.

**Conclusion:** Clinicians should not downplay the importance of aquatic occupations and hobbies in patients who exhibit positive PPD and gold QuantiFERON test. Healthcare providers should consider NTM infection in their differential diagnosis when examining patient populations exposed to aquarium water, saltwater, and freshwater environments. Preventative apparel like waterproof gloves can protect the exposed skin from infection. Clinicians can prevent NTM infections by increasing awareness and promoting prevention measures in at-risk populations, particularly since infection can be prevented with appropriate protective attire. ■

**Type:** Case Report

**Background:** Transarterial chemoembolization (TACE) is a commonly used embolotherapy for unresectable hepatocellular carcinoma (HCC). The hepatic artery is usually the vessel of choice, however, up to 30% of HCCs can develop an extrahepatic collateral (EHC) supply and failure to recognize EHC can lead to treatment failure. The most common extra hepatic artery supplying HCC is the inferior phrenic artery (IPA), with right IPA and left IPA comprising up to 83% and 12% of all collaterals respectively. Certain imaging features can help predict the presence of IPA collaterals and should be considered at the time of treatment.

**Methods:** We reviewed one recurrent HCC after radioembolization and one residual HCC after chemoembolization to identify tumor characteristics associated with the formation of EHC, especially IPA collaterals. Procedural considerations during IPA embolization and common complications are also reviewed.

**Results:** Several factors raise the suspicion for EHC development, including large size, location (segment VII), and prior arterial embolization. Avoiding non-target embolization is crucial in treatment planning as inferior phrenic artery supplies the diagram, and rarely, the pericardium and bowel. Prophylactic embolization to non-tumor feeding branches can limit non-target embolization.
Conclusion: Prompt recognition of extrahepatic collaterals of HCC plays a key role in increasing the efficacy of TACE. The most common collateral supply is from the inferior phrenic artery. Several imaging clues often suggest potential development of parasitic blood supply, and in such cases we recommend IPA angiography be performed during TACE procedures. Prophylactic embolization of non-tumor feeding IPA branches is important in avoiding non-target embolization.

Type: Original Research

Background: Cytokines and chemokines (cytokines) are central to RA pathogenesis, a fact underscored by the emergence of multiplex immunoassays for quantifying cytokine values. Intrinsic factors to rheumatoid arthritis (RA), namely rheumatoid factor (RF), may interfere with assay outcomes by nonspecifically binding detection analytes. Thus, we evaluated the performance of a commercially available multiplex platform and assessed the impact of RF depletion.

Methods: Forty-five cytokines were tested using the Meso Scale Discovery V-PLEXTM immunoassays and serum from 40 RA and 40 osteoarthritis (OA) patients. Select samples were depleted of RF using a commercial binder. Performance was assessed using intraassay coefficients of variation (CV), intraclass correlation coefficients (ICC), percent change following RF depletion, and discriminative ability between RA and OA.

Results: Of the 44 cytokines analyzed in duplicate, 22 yielded CVs <10%; only 3 demonstrated ICCs >30%. ICCs universally exceeded 0.85 with the exception of seven analytes. RA depletion altered cytokine values by <15% for 28 analytes with larger changes (>30%) seen for nine analytes. Of the 45 analytes tested, 24 differed based on measurement in plasma vs. serum. Analytes were frequently greater in RA vs. OA, but

![Figure 1](image-url)

**Figure 1. Mean absolute percent change in analyte concentration following RF depletion.**

* Wilcoxon signed-rank test p-value < 0.05  ** Wilcoxon signed-rank test p-value < 0.01

Of the 45 analytes, 28 exhibited <15% change, eight showed intermediate changes (15-30%), and nine demonstrated >30% change. RED lines indicate cut off points.
