**Mentors:** Matthew Mormino, Justin Siebler

**Program:** Orthopaedic Surgery Residency Program

**Type:** Case Report

**Background:** Although lateral locking plates are often a preferred and successful fixation construct for the treatment of periprosthetic proximal and distal femur fractures, certain complications and modes of failure have been well-described with their use. We experienced two cases of a unique mode of failure in the Non-Contact Bridge Periprosthetic Plating System (Zimmer Biomet) in which a nonlocked screw fretted through the annular seating of the plate. Appropriate patient consent was obtained for the use of these cases for educational purposes.

**Case 1:** An 85-year-old woman with a history of dementia and osteoporosis sustained a right proximal femur periprosthetic fracture after suffering a ground level fall. Open reduction and internal fixation were performed and there were no identified complications on radiographs obtained 7 weeks post-operatively. Radiographs obtained 11 weeks post-operatively demonstrated fretting of the distal-most screw through the plate (Fig. 1a).

**Case 2:** A 73-year-old man with a history of multiple myeloma, diabetes, and chronic left lower extremity weakness sustained a right periprosthetic supracondylar distal femur fracture after suffering a ground level fall. Open reduction and internal fixation was performed and there were no identified complications on radiographs obtained 8 weeks post-operatively. Radiographs obtained 14 weeks post-operatively demonstrated fretting of the distal-most screw placed proximal to the fracture site (Fig. 1b).

**Conclusion:** Periprosthetic fractures are complex orthopaedic injuries. Lateral locking plates are often the preferred treatment because of their excellent stability and ability to be placed in a minimally invasive manner. Plate or screw fracture and screw pull-out are well-documented complications, however no literature exists demonstrating the unique mode of failure exhibited in our clinical cases.

Notification of High-Risk Opiate Prescriptions Reduces Dangerous Practices
A. Beck¹, W. Zeger¹, C. Johnson², K. Baack¹, H. Nichols¹

²Nebraska Medicine

**Mentor:** Wesley Zeger

**Program:** Emergency Medicine Residency Program

**Type:** Original Research

**Background:** The U.S. is still experiencing an opioid epidemic. Current guidelines from the Centers for Disease Control (CDC) recommend no more than 50 Morphine Milligram Equivalent (MME) per day for initial prescriptions, but familiarity with conversion may be preventing providers from following these guidelines. A standard (MME) calculator was implemented in our Electronic Health Record. We sought to determine whether inclusion of this calculator and an associated warning for prescriptions above 50 MME were effective in reducing high-risk opiate prescriptions.

**Methods:** An IRB approved this study. A retrospective chart review was performed, and all opiate prescriptions from the emergency department for three months preceding and three months following the calculator was included. Discharge prescriptions were then converted to MME per day utilizing the CDC’s conversion table. Statistical calculations were performed with a two-sample T-test with unequal variance and Chi-Square statistic in Excel.
